Abstract:

This document describes the using the Overture CgMx time-domain Maxwell solver for optimization problems. The initial version uses some simple optimization routines from Matlab.

1 Introduction

We consider using the time-domain solver for Maxwell's equations, CgMx [1] to solve some optimization problems.

The optimizer is built with a few Matlab functions:

- optimizer.m: simple optimizer using Matlab functions.
- runMaxwell.m: run CgMx for a given case, and given parameters, and return appropriate results.

2 Minimizing the reflection coefficient of a slab

Consider a dielectric block with (ϵ_1, μ_1) occupying the region $x \in [-W/2, W/2]$ embedded in a material with (ϵ, μ) .

Figure 1: Dielectric block.

Figure 2: Grid and sample solutions for the dielectric block, $k_x = 1$, $\epsilon = 8$.

2.1 Minimizing the reflection coefficient of a slab by varying ϵ_1

For this example we attempt to find the value of ϵ_1 that minimizes the reflection coefficient. The analytic solution has one minimum at $\epsilon_1 = 4$ for this case (there are others, see Fig.3).

Notes:

- 1. the incident plane wave has a wave number of $k_x = 1$.
- 2. the width of the slab is W = .5 (the grid actually occupies $x \in [-.25, .25]$).
- 3. the grid can be made with the Makefile (make dielectricBlock2d).
- 4. a special user defined probe is used in this case that estimates the reflection and transmission coefficients.
- 5. Typical output from a CgMx run is shown in Fig. 4 where the reflection and transmission coefficients are shown over time. Once the solution has reached a near time-periodic state the coefficients become constant in time.

Figure 3: Dielectric block: reflection and transmission coefficients versus ϵ_1 for W = .5 from the analytic solution.

Figure 4: Dielectric block: reflection and transmission coefficients versus time as computed by CgMx. Shown are the real and imaginary parts of R and T, along with their magnitudes. The magnitude of the reflection coefficient at the final time is optimized.

Here is the output from optimizer.m with messages from the Matlab function fminsearch. A value of $\epsilon_1 = 3.975$ is obtained satisfying the tolerances.

```

2.2 Minimizing the reflection coefficient of a slab by varying the width

For this example we attempt to find the value of the block width W that minimizes the reflection coefficient. The analytic solution has one minimum at W = .5 for this case (there are others).

Here is the output of a run. The optimizer fminsearch finds the value of W = .495 satisfying the tolerances.

```

3 Adjusting the shape of a lens

In this example the shape of a *lens* is adjusted to achieve some objective. The curves defining the left and right edges of the lens are defined with NURBS curves. The shape can be controlled by adjusting the control points of the NURBS.

Figure 6 shows a Nurbs curve with control points. The curve was defined by a set of points that were interpolated to form the Nurbs.

Note: It is possible to change the control points explicitly, but there is currently a problem in that the parameterization of the curve (which is usually based on arclength) is not updated – this can result in a poor quality grid. This needs to be fixed before more general changes to the control points will be viable.

Figure 5: Target lens shape and solution (E_y) .

Figure 6: Left: Nurbs curve for lens shape with control points. Right: sequence of grids for optimization of the shape of a lens (adjusting the left and right faces of the lens).

Figure 6 shows the results of a simple test. The code was first run with a given lens shape and the transmission coefficient (averaged over a box to the right of the lens) was saved as the *target transmission* coefficient (see Figure 5). The objective of the optimization was then to start from a different lens shape and adjust the central control points on the left and right faces of the lens to match the target transmission coefficient.

Here are shome of the output from the optimizer using fminsearch

Figure 7: Convergence history of fminsearch.
